The electrons generated by the electron gun are accelerated and irradiate the sample. The electron has a kinetic energy proportional to the accelerating voltage. The kinetic energy dissipated within the sample generates characteristic signals from the specimen. The characteristic X-rays are the information used for EDS analysis.

If the incident electrons have sufficient acceleration and then have enough energy to strike an electron from the inner shell of the atom, it'll make an electron hole. An electron from the outer shell will fill up the hole and then, some characteristic X-rays will be emitted. The characteristic X-rays have different energy for each element, and the intensity will be proportional to the element concentration.

The continuum X-rays are emitted when the primary electrons are decelerated by the strong electric field existing close to atomic nucleus. The continuum X-rays have the energy of the kinetic energy lost during the deceleration. It will be observed as EDS spectrum background.

Information from specimen

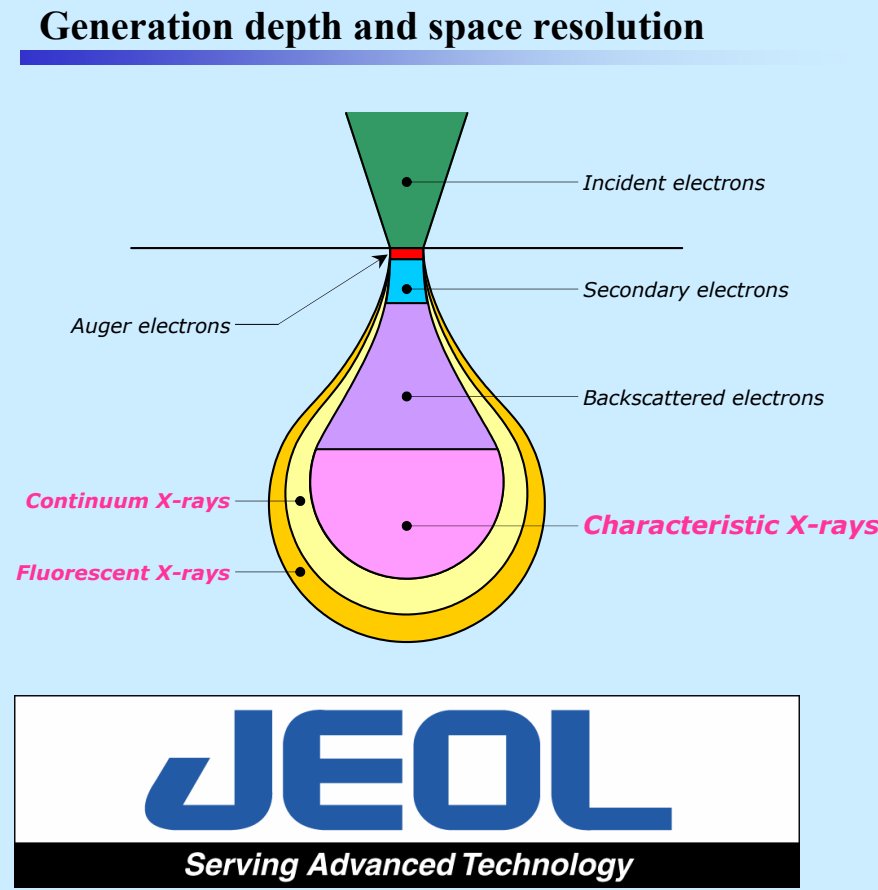

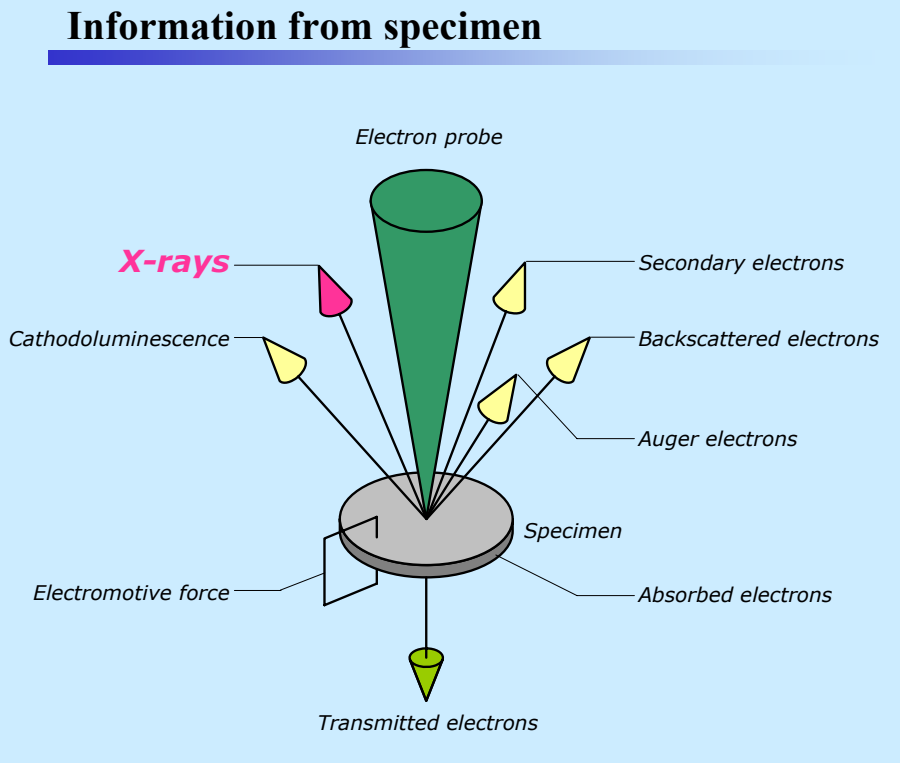

Number: 79, Name: Gold, Symbol: Au, Atomic mass: 196.97, Density (kg/m³): 19.3, Characteristic X-ray (keV): 9.712 (K α), 2.120 (M)

Minimum accelerating voltage

Unable to detect, 5kV or higher, 10kV or higher, 15kV or higher

Note: Density * 'C' as (graphite), 'P' as (white), 'S' as (alpha), 'Sn' as (white)

The colors mean to detect the characteristic X-ray of the lowest energy for each element.

Analytical area

Castaing's formula

$$Z_m = 0.033 (E_0^{1.7} - E_C^{1.7}) \frac{A}{\rho Z}$$

E₀: Accelerating voltage (kV)
E_C: Minimum emission voltage (keV)
A: Atomic mass
 ρ : Density (kg/m³)
Z: Atomic number

Analytical area of iron in 20kV $\approx 1.5 - 0.2 = 1.3 (\mu\text{m})$
